Type conversion:

In python its impossible to compute certain operations due to the types involved. for instance, you can't add two strings

containing the numbers 2 and 3 together to produce the integer 5.

as the operation will be performed on strings, making the result '23'.

Another example of type conversion is turning user input to numbers to allow for the performance of calculations

Concatenation:

As with integers and floats strings in python can be added, using a process called concatenation which can be done on any two strings. when concatenating strings it doesn't matter whether they are single or
